Overview

- **Patterns of human genetic variation**
 - Among populations
 - Among individuals
- **“Race” and its biomedical implications**
- **Linkage disequilibrium, the HapMap project, and the 1000 Genomes project**

Human Genetic Variation: Applications

- **Deciphering human history**
- **Inferring individual ancestry**
- **Forensics**
- **Finding and understanding disease-causing genes**

Mutation and Genetic Variation

Human mutation rate is $1.0 - 2.5 \times 10^{-8}$ per bp per generation: we transmit 30-75 new DNA variants with each gamete (J. Roach *et al.*, 2010, *Science*; D. Conrad *et al.*, 2011, *Nature Genetics*)

“The capacity to blunder slightly is the real marvel of DNA. Without this special attribute, we would still be anaerobic bacteria and there would be no music.”

- Lewis Thomas

How much do we differ?

(number of aligned DNA base differences)

| | | |
|--------------------|---|-----------|
| ■ Identical twins |  | 0 |
| ■ Unrelated humans |  | 1/1,000 |
| ■ Human vs. chimp |  | 1/100 |
| ■ Human vs. mouse |  | 1/6 - 1/3 |

■ 3 billion DNA bases → 3 million differences (single nucleotide polymorphisms; SNPs) between each pair of haploid human DNA sequences

Copy number variants (deletions/duplications > 1000 bp) account for as much variation as do single-nucleotide variants

The conventional view is that we have two copies of all genes except those on the sex chromosomes...

Pair of chromosomes

Gene copy number

...but random duplications and deletions of large segments of DNA mean the number of copies of many genes varies

Gene copy number

Each human is heterozygous for at least 100 CNVs (3 Mb).

How much do populations differ?

Map labels and photos:

- Iran (26)
- Buryat (25)
- Kyrgyzstan (25)
- Iraqi Kurds (25)
- Pakistanis (25)
- Nepalese (25)
- Thai (25)
- Bambara (25)
- Dogon (24)
- Tongan (13)
- Bolivian (23)

Photos show individuals from these populations: a couple in Iran, a woman in Buryat, a woman in Kyrgyzstan, a woman in Iraqi Kurdistan, a woman in Pakistan, a woman in Nepal, a woman in Thailand, a woman in Bambara, a woman in Dogon, a group in Tonga, and a woman in Bolivia.

Allele frequencies in populations

| Population | SNP 1 | SNP 2 | SNP 3 |
|------------|-------|-------|-------|
| 1 | 0.588 | 0.890 | 0.880 |
| 2 | 0.671 | 0.559 | 0.528 |
| 3 | 0.792 | 0.790 | 0.828 |

1/1000 bp varies between a pair of individuals: how is this variation distributed between continents?

$$F_{ST} = \frac{H_T - \bar{H}_S}{H_T}$$

F_{ST} is the amount of genetic variation that is due to population differences

H_T is the total heterozygosity (variation) in the sample

H_S is the average heterozygosity within each population (continent)

$F_{ST} = 0$: All variation exists within populations; none exists between

$F_{ST} = 1$: All variation exists between populations

1/1000 bp varies between individuals: how is this variation distributed among continents?

| | 60 STRs | 30 RSPs | 100 <i>Alus</i> | 75 L1s | 250K SNP | |
|--|---------|---------|-----------------|--------|----------|--|
| Between individuals, within continents | 90% | 87% | 86% | 88% | 88% | |
| Between continents (F_{ST}) | 10% | 13% | 14% | 12% | 12% | |

Jorde et al., 2000, *Am. J. Hum. Genet.*
Xing et al., 2009, *Genome Res.*

1/1000 bp varies between individuals: how is this variation distributed among continents?

| | 60 STRs | 30 RSPs | 100 <i>Alus</i> | 75 L1s | 250K SNP | Skin Color |
|--|---------|---------|-----------------|--------|----------|------------|
| Between individuals, within continents | 90% | 87% | 86% | 88% | 88% | 10% |
| Between continents (F_{ST}) | 10% | 13% | 14% | 12% | 12% | 90% |

Jorde et al., 2000, *Am. J. Hum. Genet.*
J. Xing et al., 2009, *Genome Res.*

% SNP minor alleles shared among four major regions (Africa, Europe, E. Asia, India): 250K chip results

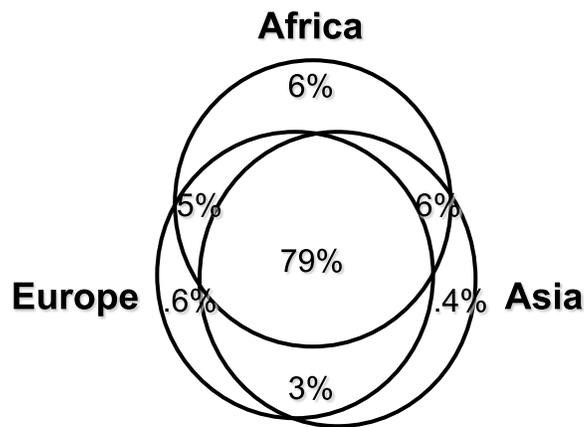

| Minor allele present in: | |
|--------------------------|-------|
| All 4 groups | 78.6% |
| At least 3 groups | 88.0% |
| At least 2 groups | 92.1% |
| Africa only | 7.4% |
| Any non-African group | 0.5% |

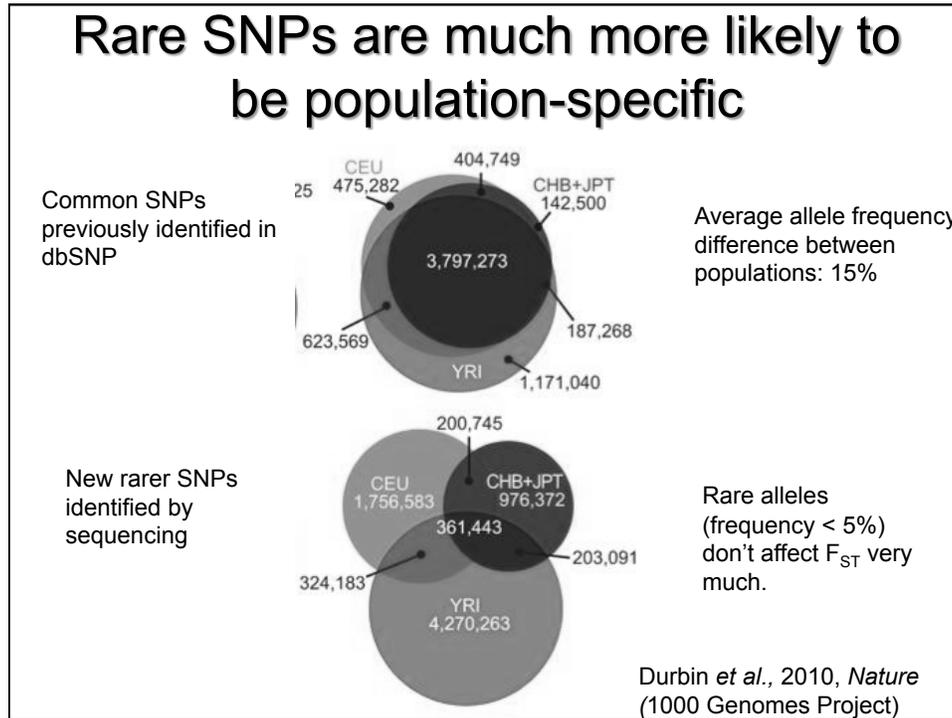

No SNPs were fixed present in one population, fixed absent in another

J. Xing *et al.*, 2010, *Genome Res.*

Most common genetic variants are shared among populations:

7,742 SNPs >.05 in ENCODE database

A simple genetic distance measure

$$D_{ij} = |p_i - p_j|$$

D_{ij} is the genetic distance between populations i and j ; p_i and p_j are the allele frequencies of a SNP in populations i and j .

| Pop. | SNP 1 | SNP 2 | SNP 3 |
|------|-------|-------|-------|
| 1 | 0.588 | 0.890 | 0.880 |
| 2 | 0.671 | 0.559 | 0.528 |
| 3 | 0.792 | 0.790 | 0.828 |

$D_{12} = |0.588 - 0.671| = 0.083$ (avg. over all SNPs)

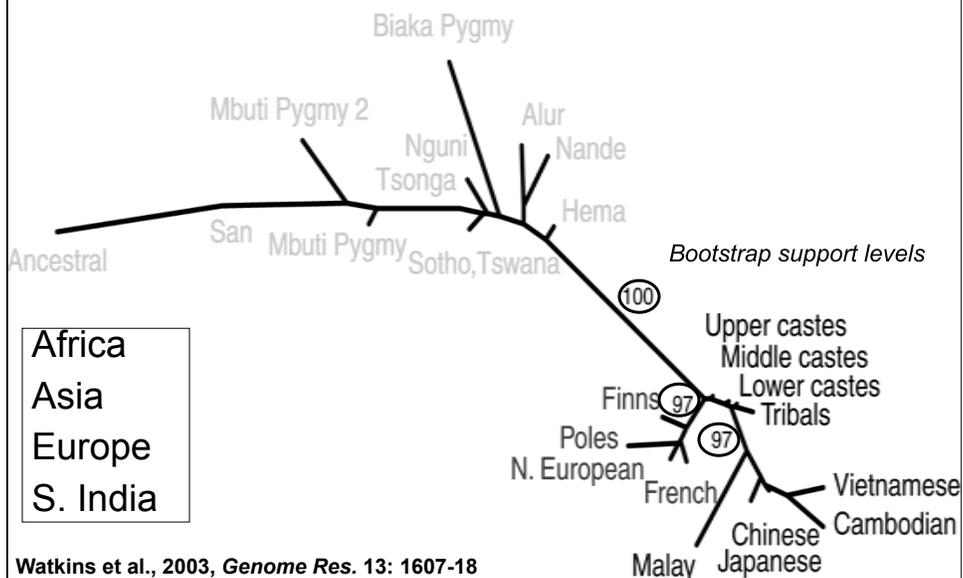

Building a population network

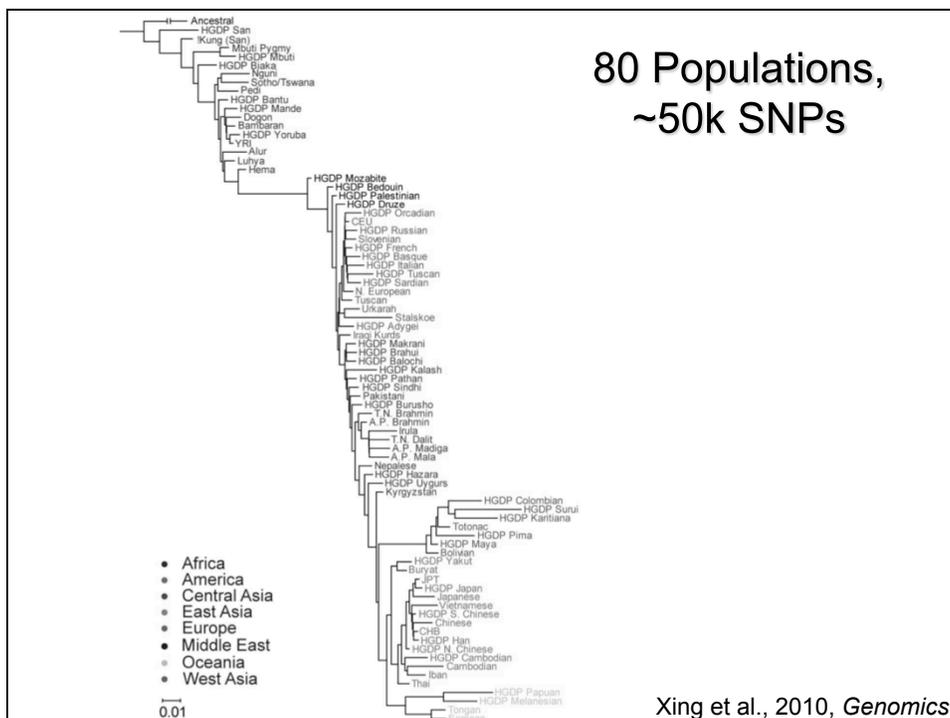

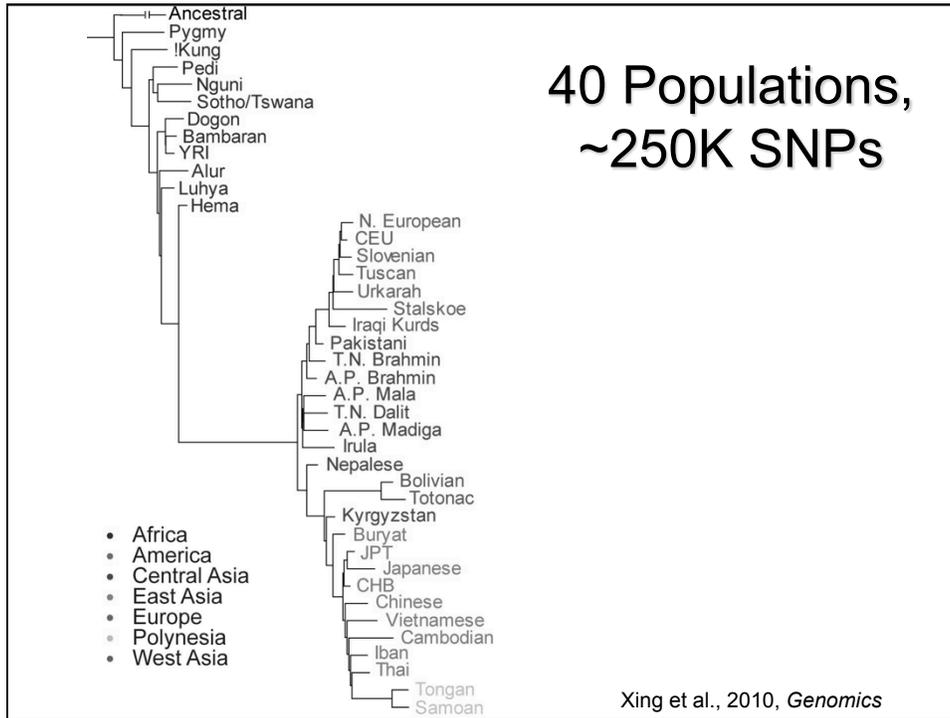

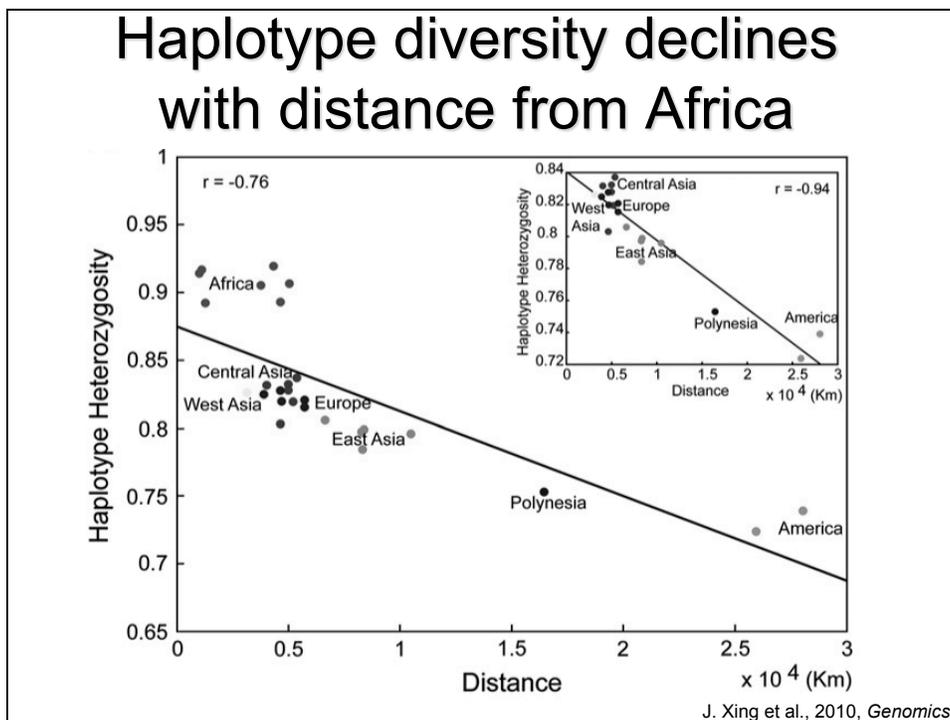

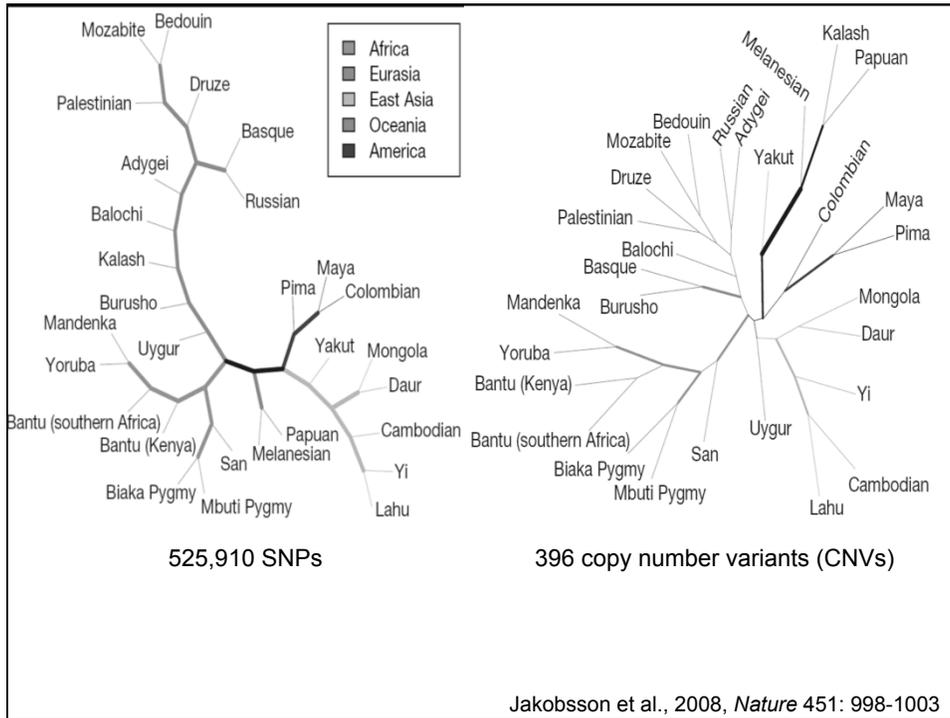

| Pop. | SNP 1 |
|------|-------|
| 1 | 0.588 |
| 2 | 0.671 |
| 3 | 0.792 |

$$|p_1 - p_2| \quad |p_3 - (p_1 + p_2)/2|$$

Genetic relationships based on 100 autosomal *Alu* polymorphisms

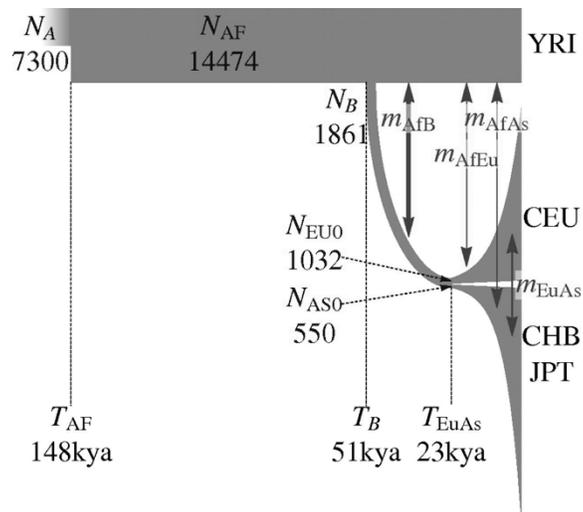

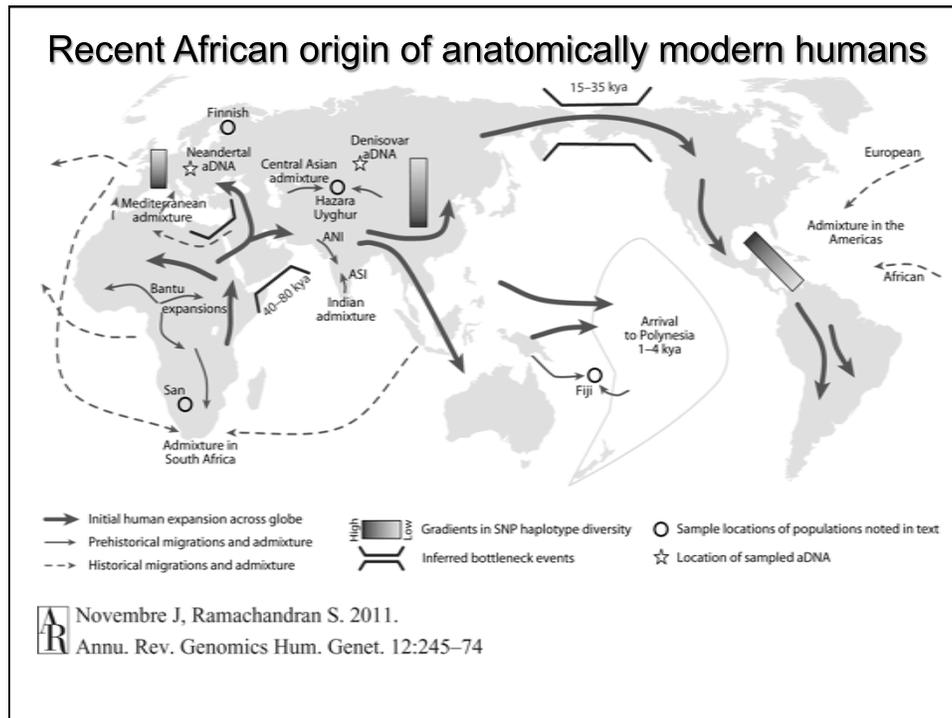

Sequence data permit more accurate inferences about population history

- Microarray SNPs are selected for higher frequency and diversity in Europeans
- Complete DNA sequences are unbiased and include information about rare variants

An inferred demographic model, with line width corresponding to population size and time flowing from left to right.

Gravel S et al. PNAS 2011;108:11983-11988

Evidence for mixture between Neanderthals and modern humans

- mtDNA sequences from 12 Neanderthal skeletons show no evidence for recent shared polymorphisms
- Evidence for mixture from nuclear sequence (1.3x coverage): 1-4% of modern human DNA has Neanderthal origins (Green et al., 2010, *Science*)
 - Only non-Africans share DNA with Neanderthals
 - Neanderthal DNA sharing is seen in all non-African populations
 - Could some of the shared sequences have adaptive significance?

What can genetics tell us about “race”?

“Race’ is biologically meaningless”

-- Schwartz, 2001, *N. Engl. J. Med.*

“I am a racially profiling doctor”

-- Satel, May 5, 2002, *New York Times*

“These [genetic] data also show that any two individuals within a particular population are as different genetically as any two people selected from any two populations in the world.”

-- American Anthropological Association, 1997

paternal line

Your Y chromosome DNA determines your paternal haplogroup. What is a haplogroup? [tell a friend](#)

[Map](#) [History](#) [Haplogroup Tree](#)

Paternal Haplogroup: I1*

I1* is a subgroup of I1, which is described below.
Locations of haplogroup I1 circa 5000 years ago, before the era of intercontinental travel.

Haplogroup I1 can be found at levels of 10% and higher in many parts of Europe, due to its expansion with men who migrated northward after the end of the Ice Age about 12,000 years ago. It reaches its highest levels in Denmark and the southern parts of Sweden and Norway.

Human Prehistory Videos

maternal line

Your mitochondrial DNA determines your maternal haplogroup. What is a haplogroup? [tell a friend](#)

Map | History | Haplogroup Tree

Maternal Haplogroup: U8a

U8a is a subgroup of U8, which is described below.

Locations of haplogroup U8 circa 5000 years ago, before the era of intercontinental travel.

Haplogroup U8 arose in the Near East about 50,000 years ago and moved into Europe not long afterward, along with the first modern humans to inhabit the continent. Limited to a few scattered localities during the Ice Age, another migration carried the haplogroup out of the Iberian Peninsula into central and northern Europe after climate conditions began improving about 15,000 years ago.

ancestry painting

Trace the ancestry of your chromosomes, one segment at a time. Last updated April 23, 2008.

Chromosome View

■ Solid segments indicate that both chromosomes come from the same geographic region. See a Cambodian Woman's painting.
 ■ Dual-colored segments indicate chromosomes from different geographic regions. See an African American Man's painting.

Select a person: **Lynn Jorde**

Solid segments indicate that both chromosomes come from the same geographic region. See a Cambodian Woman's painting.
 Dual-colored segments indicate chromosomes from different geographic regions. See an African American Man's painting.

Select a person: Berber Woman

Berber Woman ?

Berbers are native to northern Africa, a region isolated from sub-Saharan Africa by the Sahara desert. This woman shows the greatest degree of similarity to our European population, although migrations across the Sahara and from western Asia have also contributed to her ancestry, as her painting illustrates.

| | |

 Dual-colored segments indicate chromosomes from different geographic regions. See an African American Man's painting.

Select a person: African American Man

African American Man ?

Most African Americans today trace a large part their ancestry to sub-Saharan Africa as a result of the slave trade. Over the generations since, both Europeans and Native Americans have intermarried with African Americans and contributed ancestry, as seen in the ancestry painting of this man, self-identified as African American. In fact, one of this man's chromosomes appears to be fully European across the whole genome, so it is likely that one of his parents was European.

What do these findings imply for biomedicine?

- Large numbers of independent DNA polymorphisms can inform us about ancestry and population history
- Responses to many therapeutic drugs may involve variation in just a few genes (along with environmental variation)
- These variants typically differ between populations only in their *frequency* and imply substantial overlap between populations

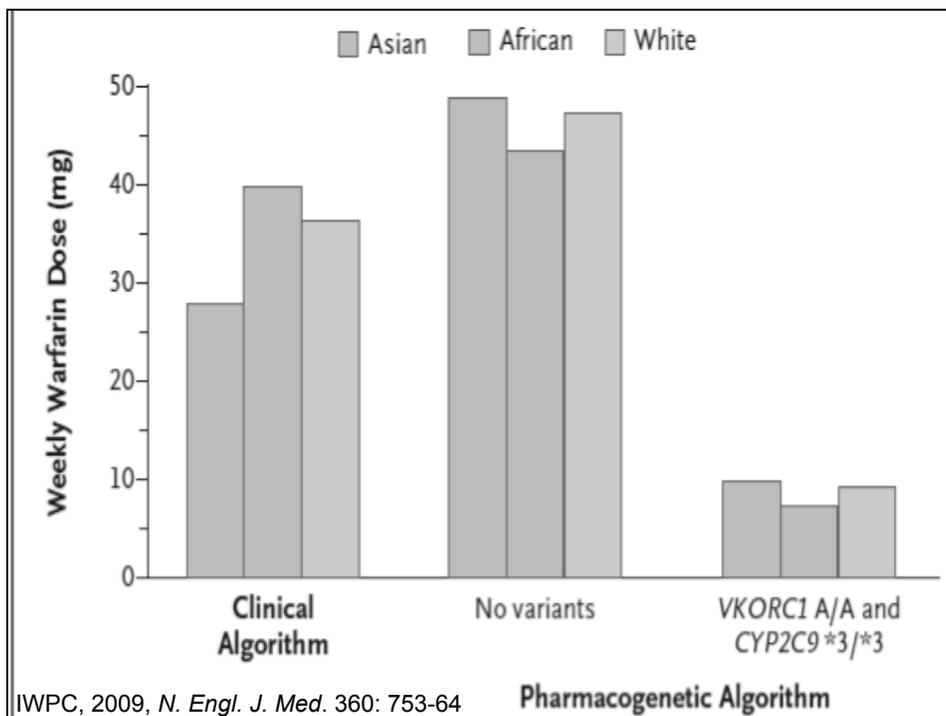

Blood pressure response to ACE inhibitors (Sehgal, 2004, *Hypertension* 43: 566-72)

EGFR inhibitors and non-small cell lung cancer

- Gefitinib and erlotinib inhibit epidermal growth factor receptor (EGFR) tyrosine kinase activity
- Effective in 10% of Europeans, 30% of Asians (Japanese, Chinese, Koreans)
- Somatic mutations in *EGFR* found in 10% of Europeans, 30% of Japanese
- 70-80% of those with mutations respond to gefitinib; <10% of those without mutations respond

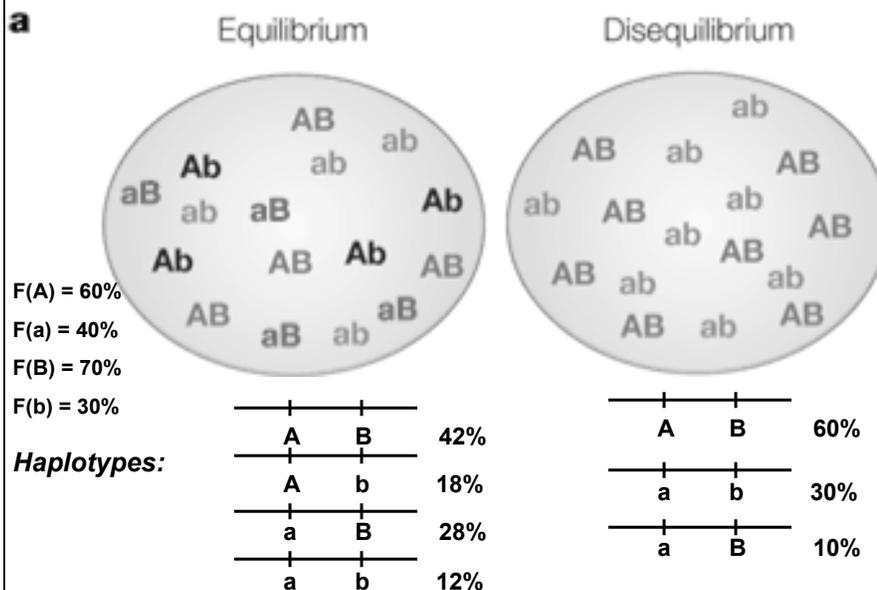

Johnson, 2005, *Cancer Res.* 65: 7525-9; McDermott et al., *N. Engl. J. Med.* 364: 340-50

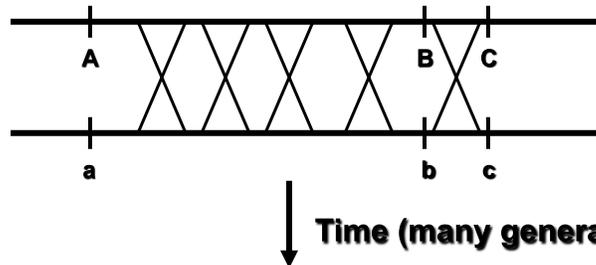

Genetic Variation and “Race”

- Genetic variation is correlated with geography and tends to be distributed continuously across geographic space
- “Race” may not be biologically meaningful, but it is biologically imprecise
- Individual ancestry provides more medically useful information

Linkage disequilibrium: nonrandom association of alleles at linked loci

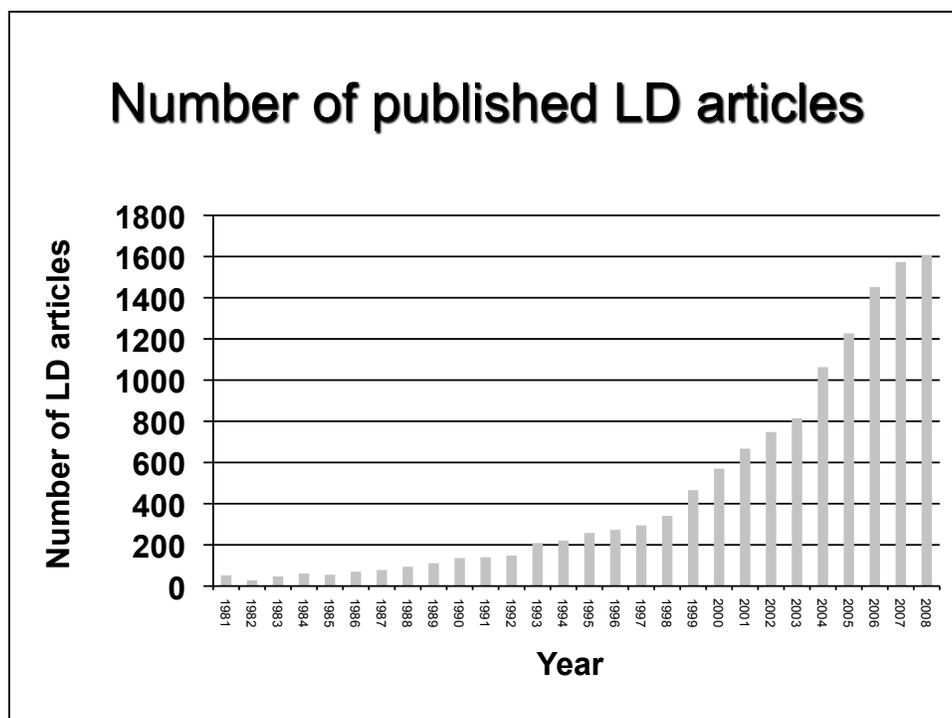

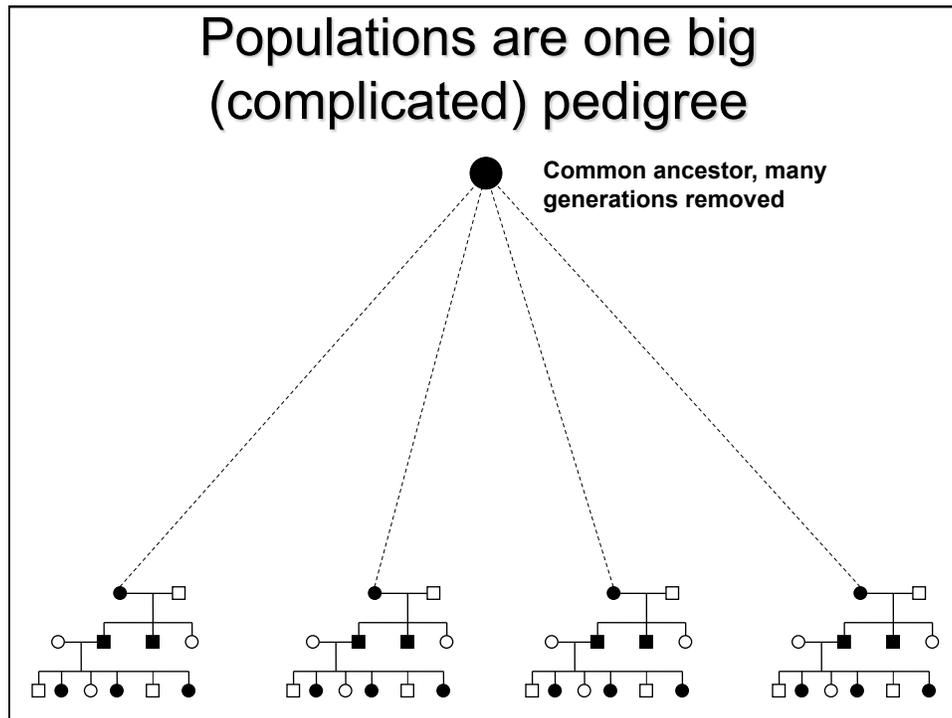

**Over time, more crossovers will occur
between loci located further apart**

**B and C will be found together on the same haplotype
more often than A and B: there is more *linkage
disequilibrium* between B and C than A and B**

Potential advantages of linkage disequilibrium (LD)

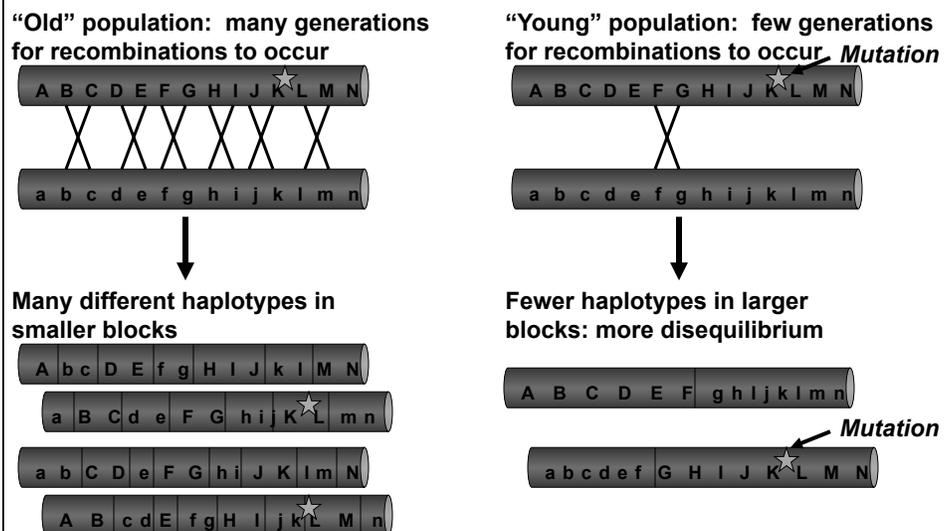

- Family data are *not* necessarily needed
- Microarray technology now exists that allows dense genotype assays (SNPs every 3 kb)
- Association studies (linkage disequilibrium) can incorporate many past generations of recombination to narrow the candidate region

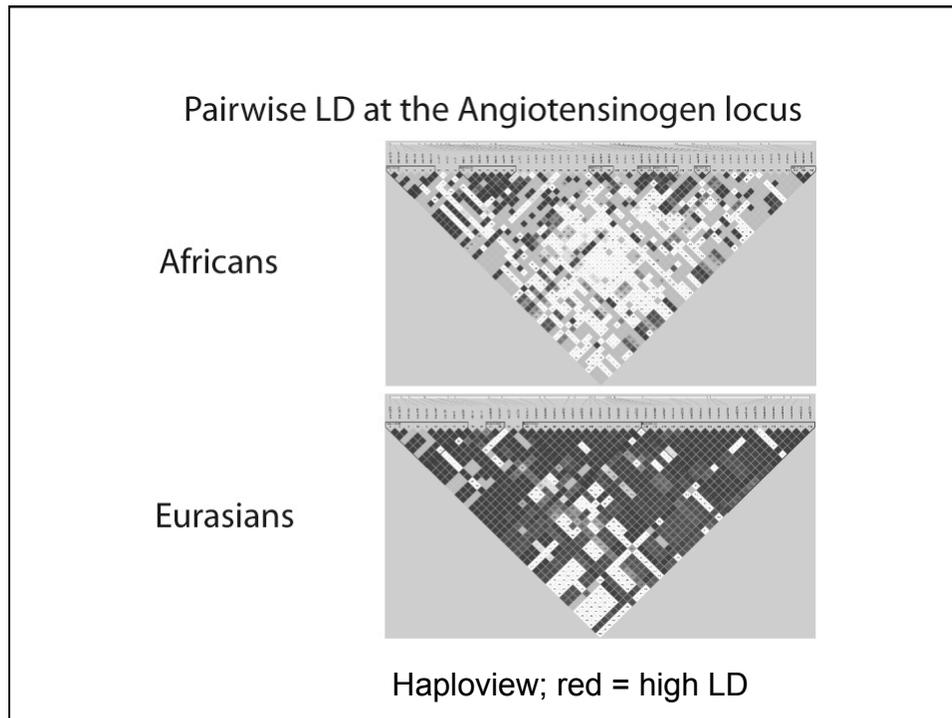

Factors that May Affect Linkage Disequilibrium Patterns

- **Chromosome location**
 - Telomeric vs. centromeric
 - Intragenic vs. extragenic
- **DNA sequence patterns (GC content; presence of *Alu* elements)**
- **Recombination hotspots (1 every 50-100 kb)**
 - 13-mer bound by *PRDM9* associated with 40% of hotspots
- **Evolutionary factors: LD varies among populations**
 - Natural selection
 - Gene flow
 - Mutation, gene conversion
 - Genetic drift

Population “age” can affect haplotype structure

How general are these patterns?

**To what extent does LD vary with
genomic location and population?**

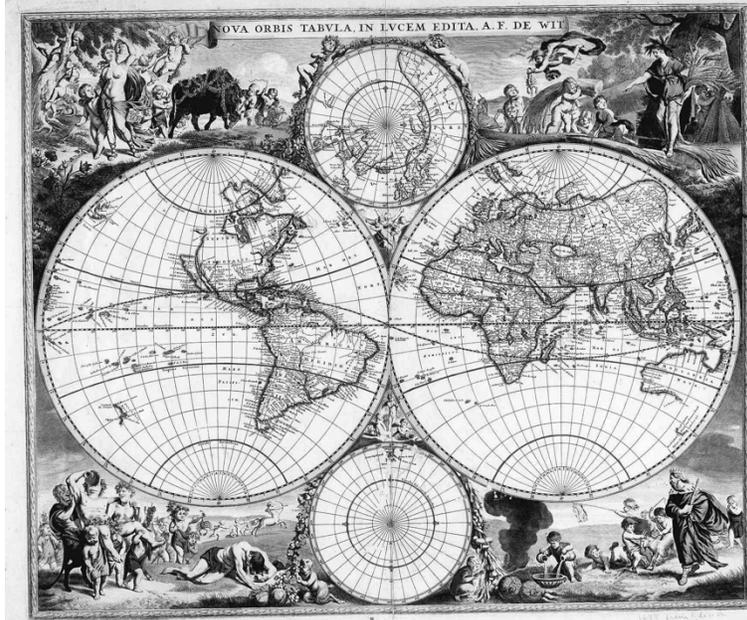

A Map of the World, 1544

In search of a better map: The International Haplotype Map Project

- 600,000 SNPs (1 per 5 kb) genotyped in 270 individuals
 - 90 CEPH Utah individuals (30 trios)
 - 90 Yoruban from Nigeria (30 trios)
 - 90 East Asians (45 Chinese, 45 Japanese)
- Evaluate patterns of linkage disequilibrium and haplotype structure
 - Variation in different genomic regions
 - Variation in different populations

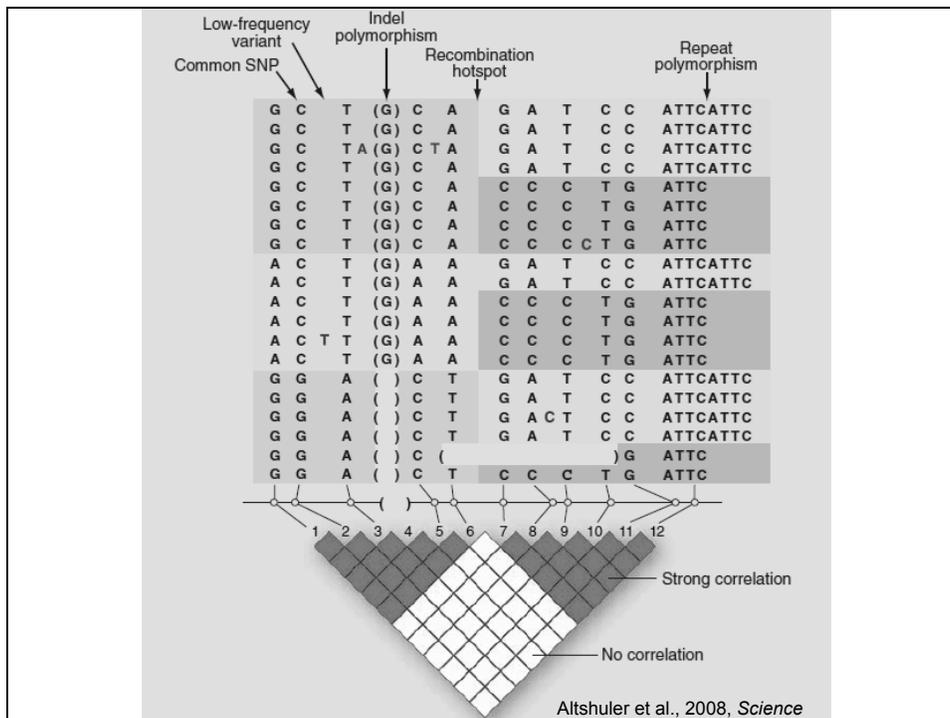

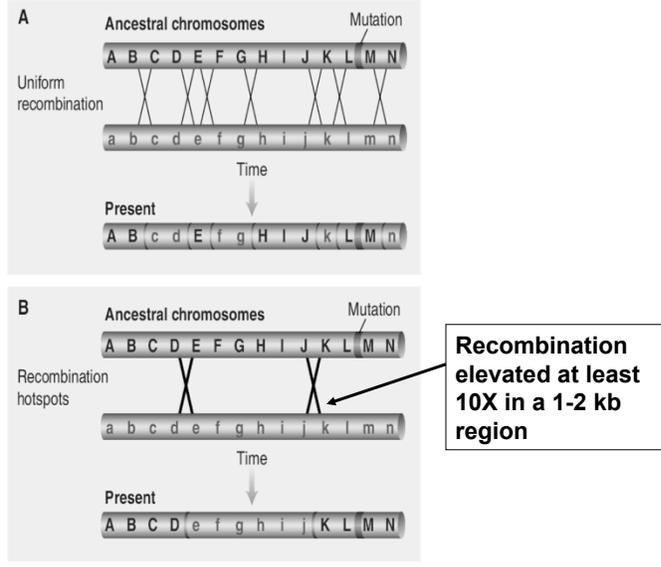

A Map of the World, 1688

Genetic applications of HapMap

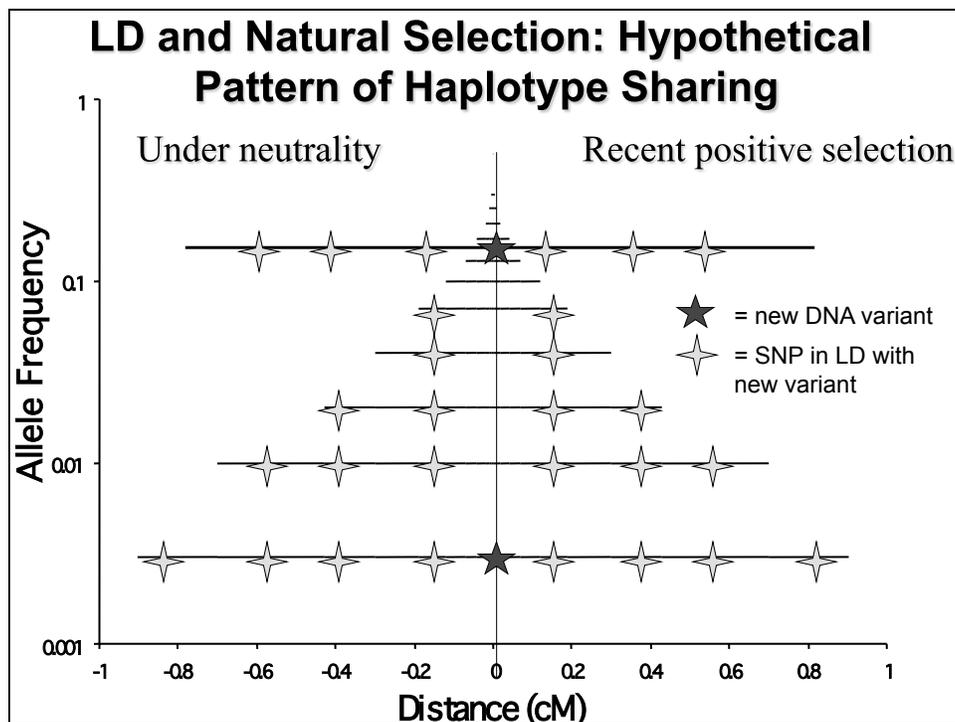

- Understanding human genome-wide haplotype diversity
- Detection of recombination hotspots
- Detection of genes that have experienced strong natural selection
- Detection of disease-causing mutations

Recombination hotspots and haplotype blocks

Recombination hotspots

- LD patterns indicate 25,000 - 50,000 hotspots in human genome (1 every 50 – 100 kb) (Myers et al., 2005, *Science*)
- 60% of crossovers occur in only 6% of the genome (Coop et al., 2008, *Science* 319: 1395-8)
- Hotspots are not congruent in human and chimpanzee, despite 99% sequence identity: suggests hotspots evolve rapidly and may not be sequence-dependent

Examples of genes in which elevated LD indicates recent natural selection

| Gene | Phenotype |
|-------------------------------|---------------------|
| G6PD | Malaria protection |
| HFE (hemochromatosis) | Iron absorption |
| CYP3A5 | Sodium retention |
| LCT (lactase enhancer) | Lactase persistence |
| SLC24A5 | Skin pigmentation |
| Alcohol dehydrogenase | Ethanol metabolism |
| EPAS1, EGLN1 | Hypoxia response |

Voight et al., 2006, *PLOS Biology* 4: 446-458

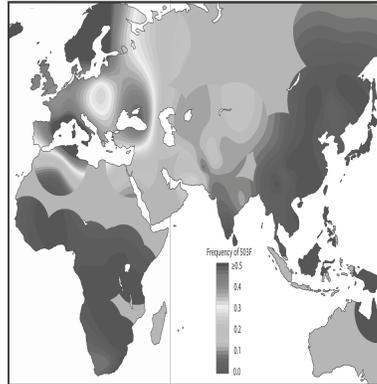

Simonson et al., 2010, *Science*

Recent Positive Selection, IBD5, and Crohn Disease

- Crohn disease is a chronic disorder of the intestinal tract with a prevalence of approximately 0.2%.
- IBD5 is a 250 kb multi-gene haplotype that is strongly associated with Crohn disease in Europeans.
- Multiple GWAS have reported association between Crohn disease and SNPs in the *OCTN1* gene in the IBD5 region.

Huff et al., 2011, *Mol. Biol. Evol.*

503F Variant of *OCTN1*

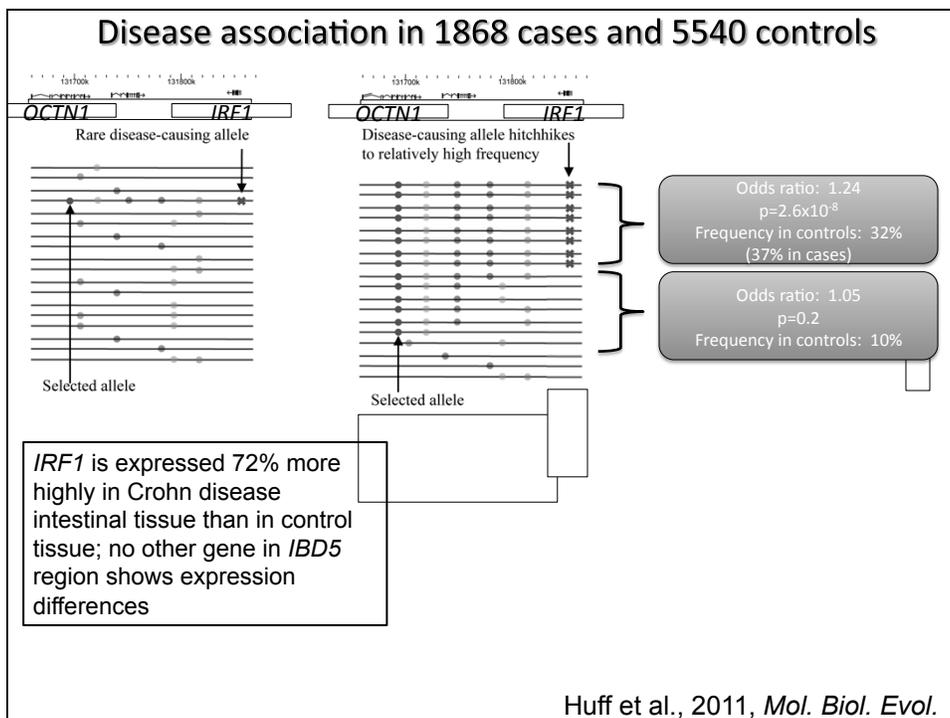

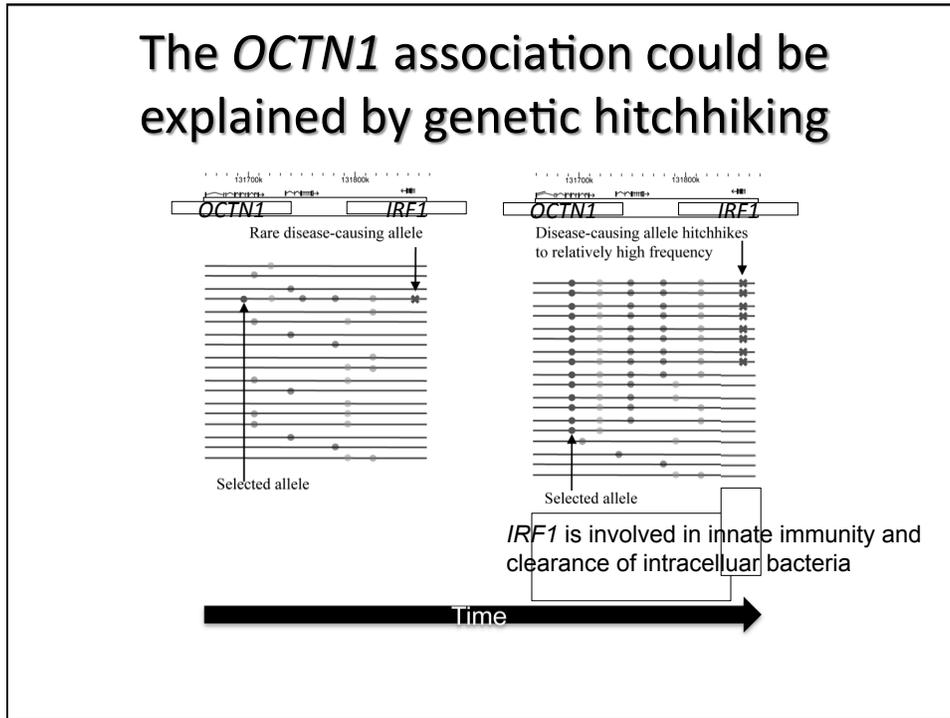

- Arose approximately 12,000 years ago; freq. 30-50% in Europe.
- 503F is a gain-of-function mutation that increases ergothioneine substrate efficiency by 300%.

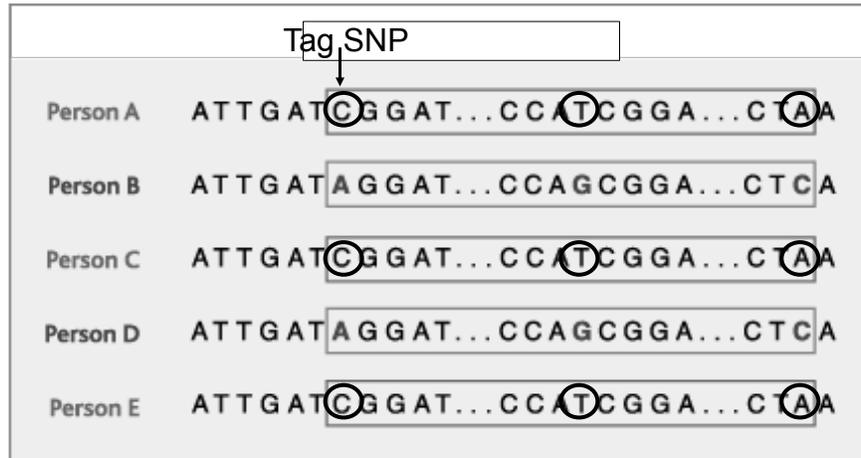

Recent Positive Selection at IBD5

| Sample | iHS | p-value |
|----------------|-------|---------|
| HapMap CEU | -3.1 | 0.0007 |
| HGDP Russian | -2.75 | 0.0044 |
| HGDP Sardinian | -2.76 | 0.0075 |
| HGDP French | -2.64 | 0.0076 |
| HGDP Basque | -2.37 | 0.0128 |

Huff et al., 2011, *Mol. Biol. Evol.*

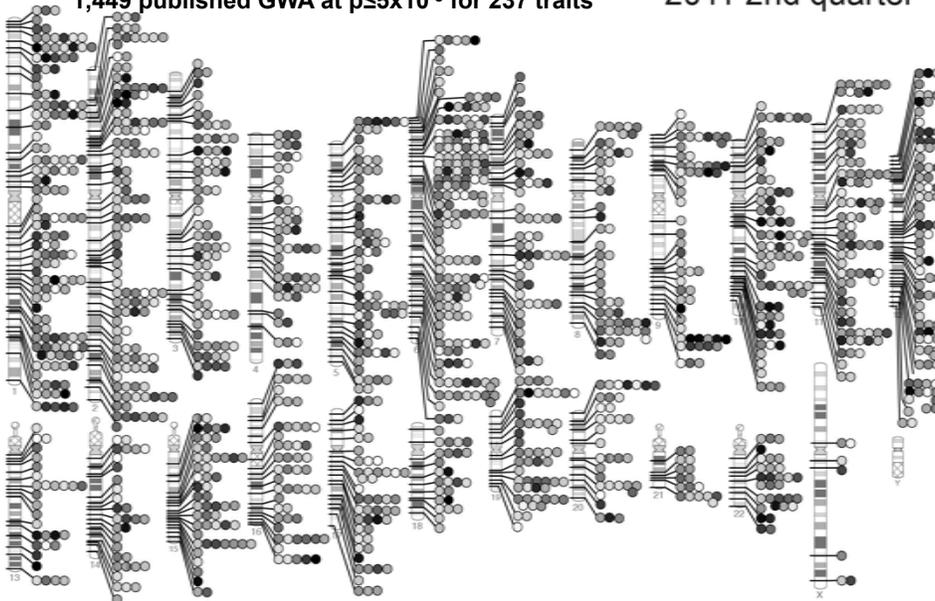

SNPs in disequilibrium are redundant: we don't need to type all of them

For genome-wide association studies, "complete" coverage is given by about 1.6 million SNPs for African populations, 600,000 to 1M SNPs for non-African populations

Published Genome-Wide Associations through 06/2011,
1,449 published GWA at $p \leq 5 \times 10^{-8}$ for 237 traits

2011 2nd quarter

Population genetics is guiding development of new sequence analysis resources

- 1000 Genomes Project
 - Provides “control sequences” for variant analysis
 - Most rare alleles are not shared among populations (Gravel *et al.*, 2011, *PNAS*)
- When is a variant functionally significant?
 - Evidence of purifying selection (elimination of deleterious variants) [Yandell *et al.*, 2011, *Genome Res.*]
 - Evolutionary conservation among species

Population genetics and genome analysis

- **Genetic variation contains useful information about population history**
- **Genetic variation provides a more informed view of “race” and its relevance to medicine**
- **Population genetic analysis has been critical in understanding linkage disequilibrium and its application in disease-gene mapping**
- **Population genetics is *fun!***
