

# Expression-based variant impact phenotyping of somatic mutations in cancer

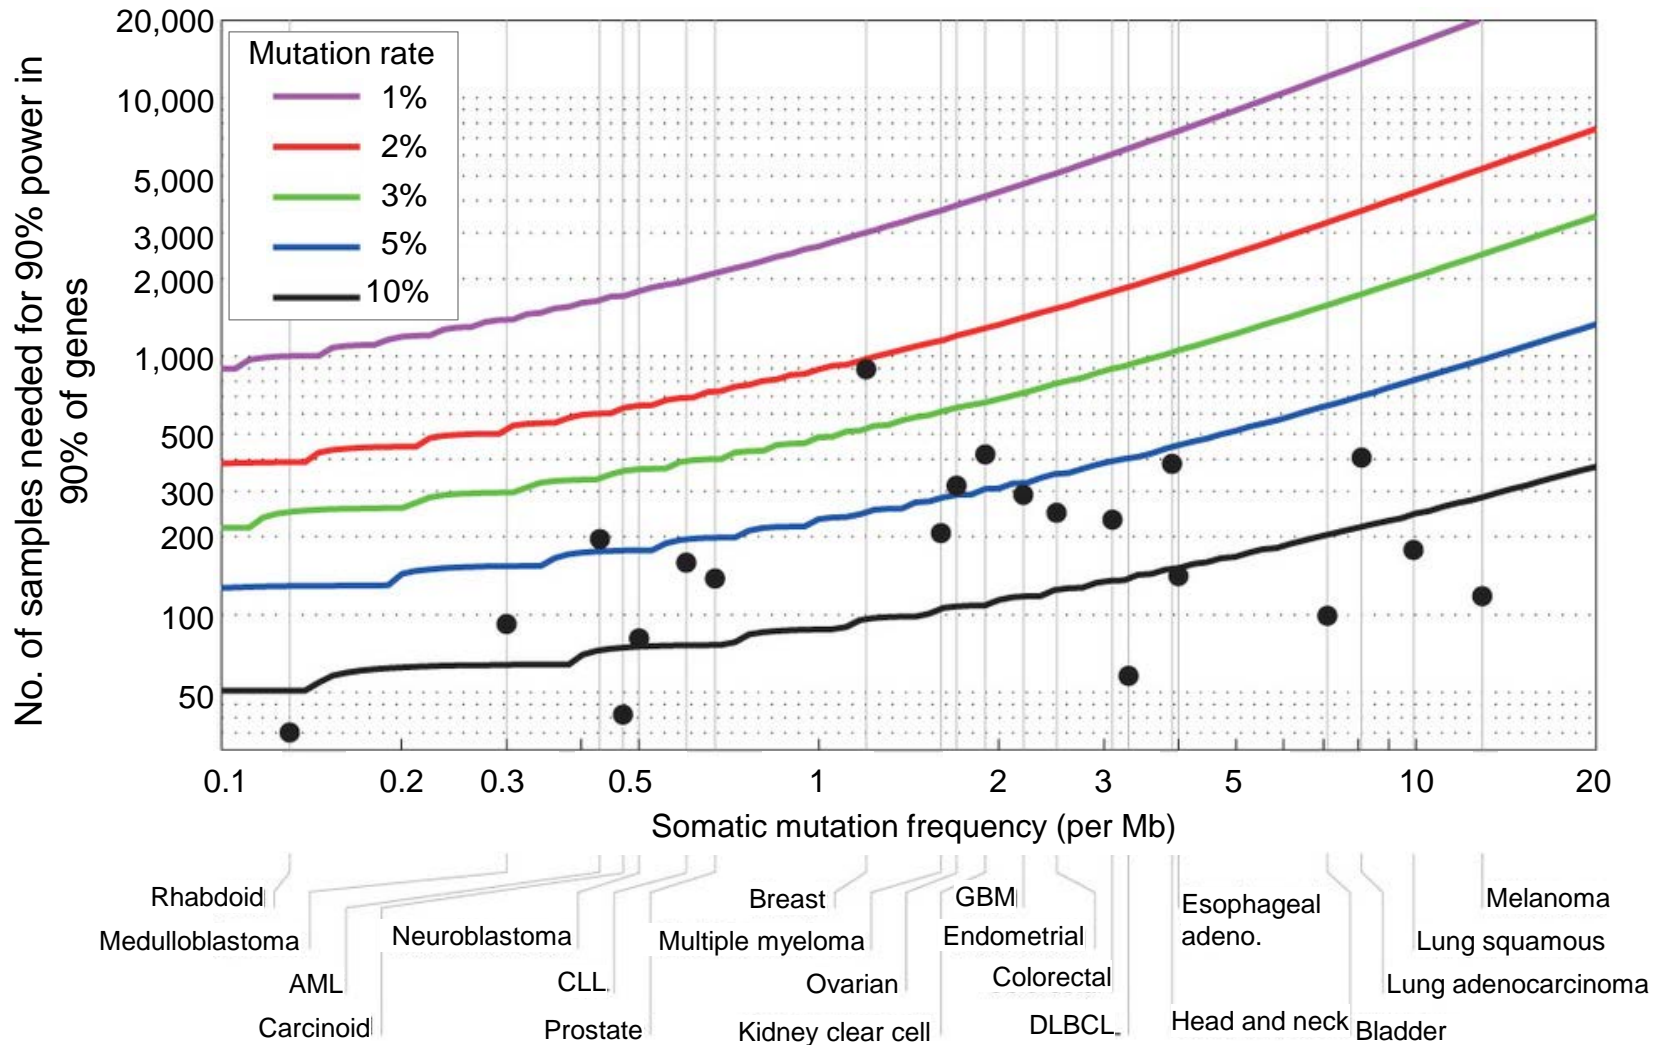

Angela Brooks, Ph.D.  
Alice Berger, Ph.D.  
Xiaoyun Wu, Ph.D.

Matthew Meyerson, M.D., Ph.D.  
Jesse Boehm, Ph.D.

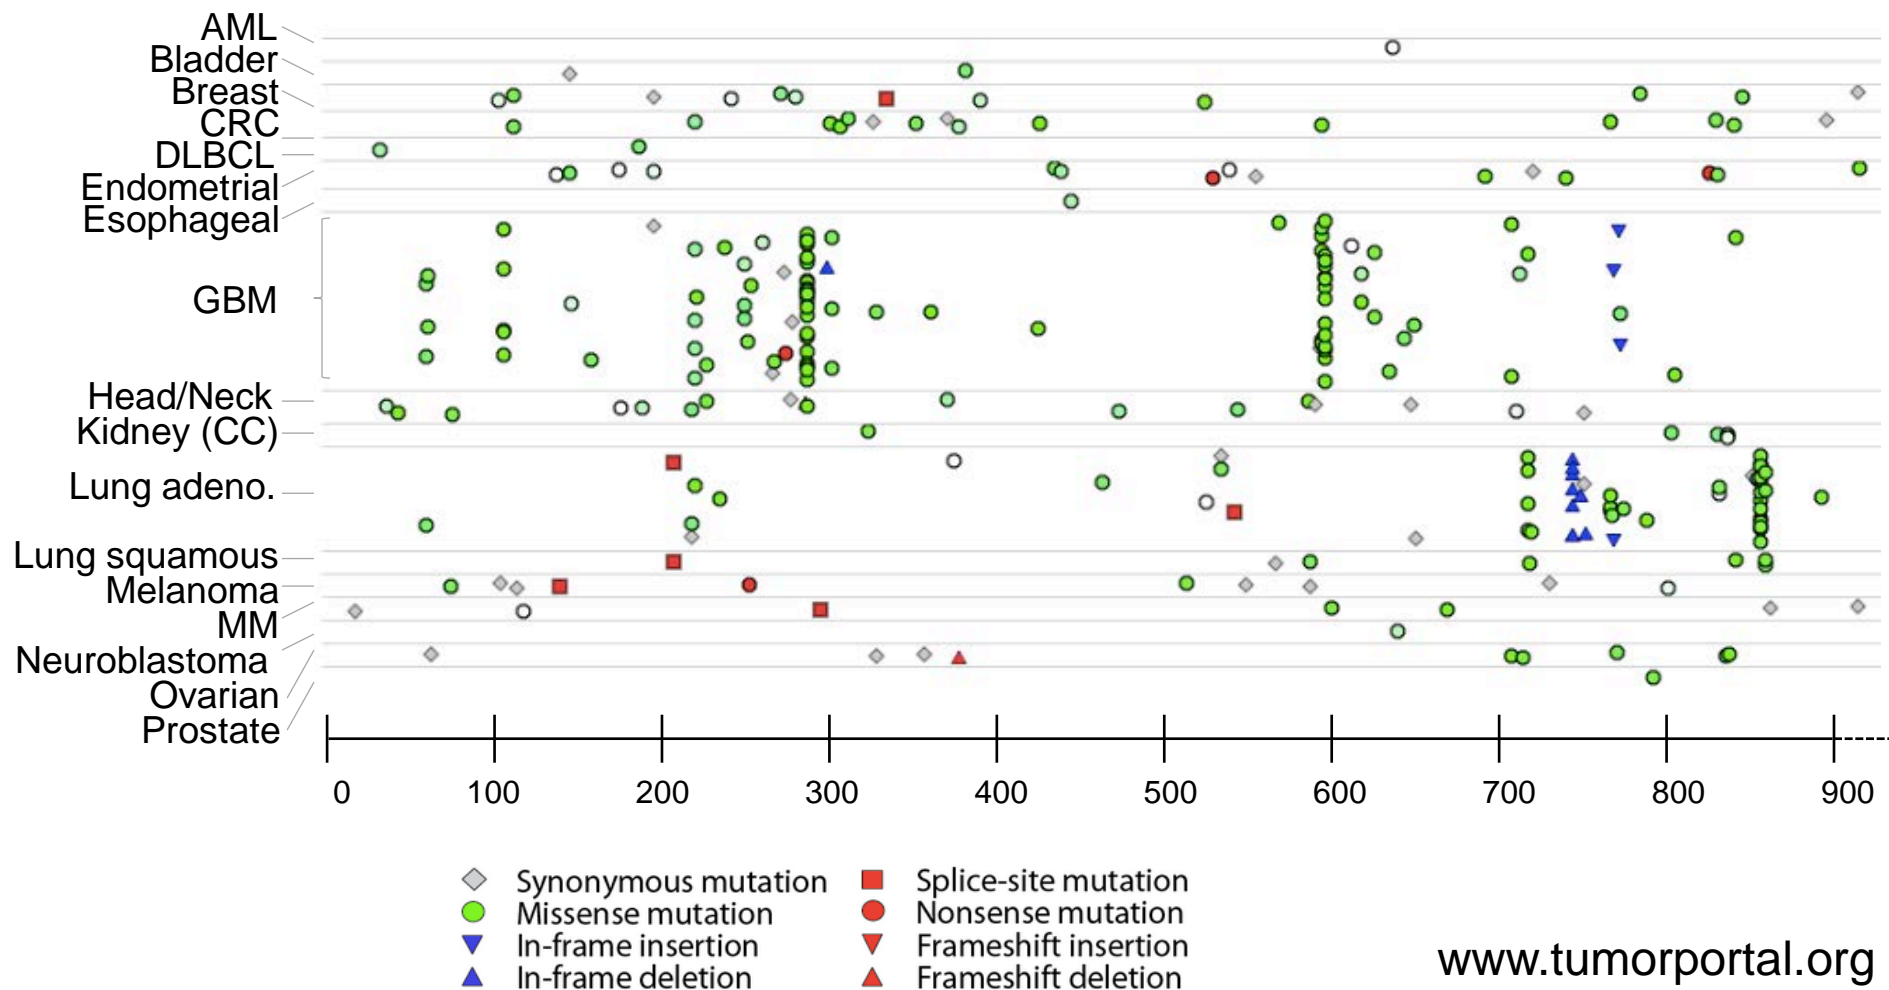

May 11, 2015

# Cancer sequencing studies are underpowered to find all functionally relevant mutated genes

# Sequencing studies are even more underpowered to find impactful variants from passengers

## *EGFR* (amino acid coordinates)

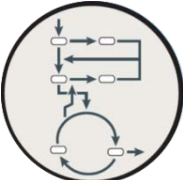

# Approaches to high-throughput experimental variant impact phenotyping

## Somatic variants from cancer genome studies

Variant-specific reagents: open-reading frame (ORF) or CRISPR

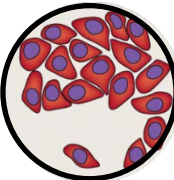

Genetic interactions

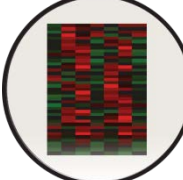

Multiplexed tumorigenesis

Pathway-specific assays

Morphologic profiling

Expression profiling

Gene-agnostic assays

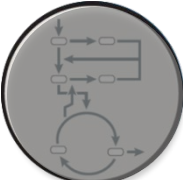

# Expression-based variant impact phenotyping

**Somatic variants from cancer genome studies**

Variant-specific reagents: **open-reading frame (ORF)** or CRISPR

**Gene-agnostic assays**

# Testing functional impact of somatic mutations in lung adenocarcinomas

# Approach: Compare gene expression changes upon introduction of WT and mutant variants

## ORF library

- 47 genes, 303 alleles
- Missense and indel variants found in >400 lung adenocarcinomas\*
  - *KEAP1*: 38 alleles + WT
  - *KRAS*: 12 alleles + WT
  - *EGFR*: 11 alleles + WT

\*Imielinski et al. 2012,  
TCGA Nature 2014

# Comparing changes in gene expression can predict variant impact

Likely inert:  
*ARAF* V145L

# Comparing changes in gene expression can predict variant impact

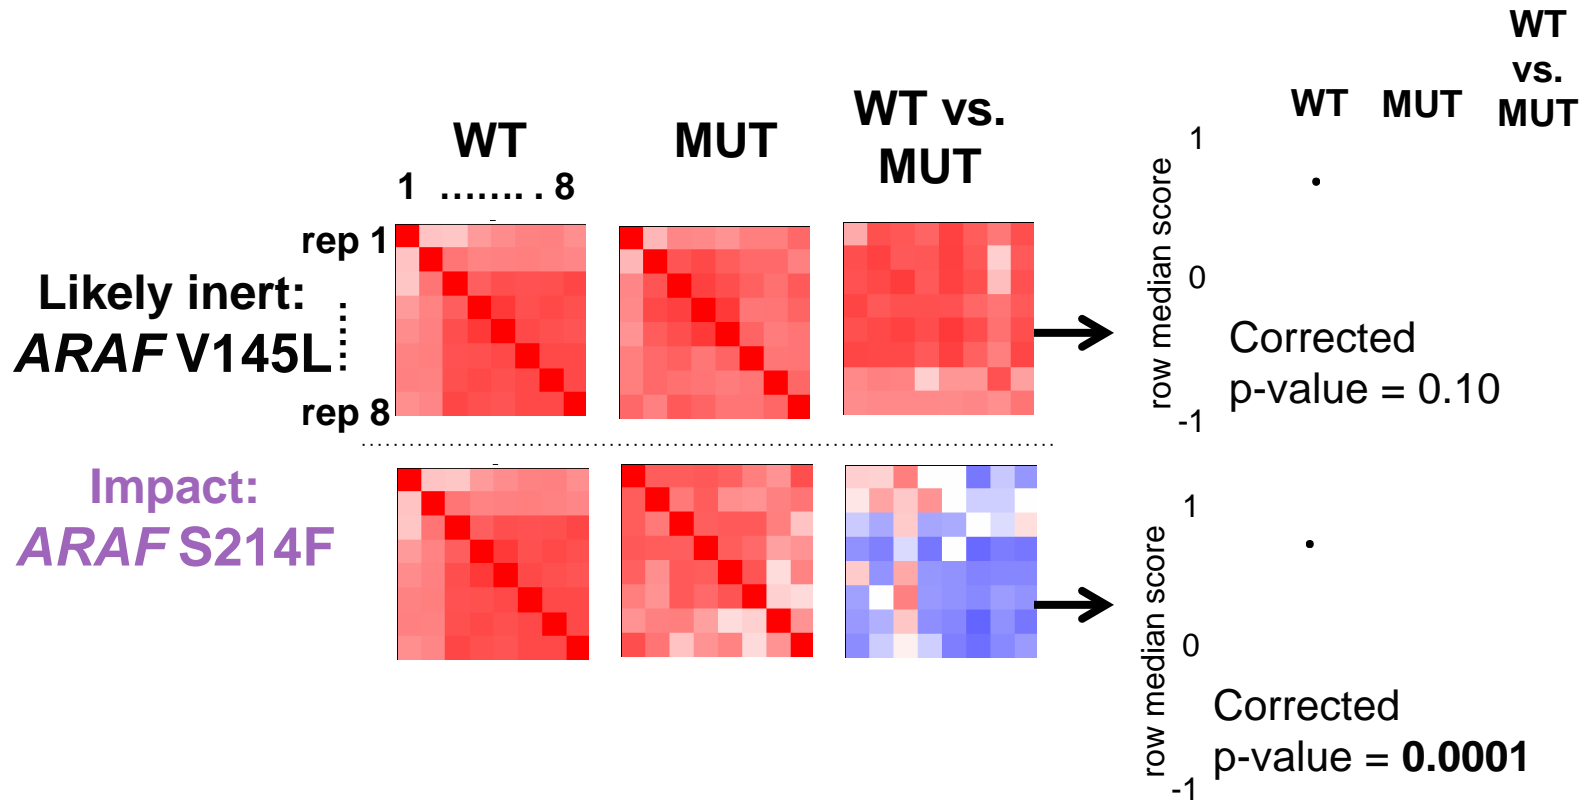

Likely inert:  
*ARAF* V145L

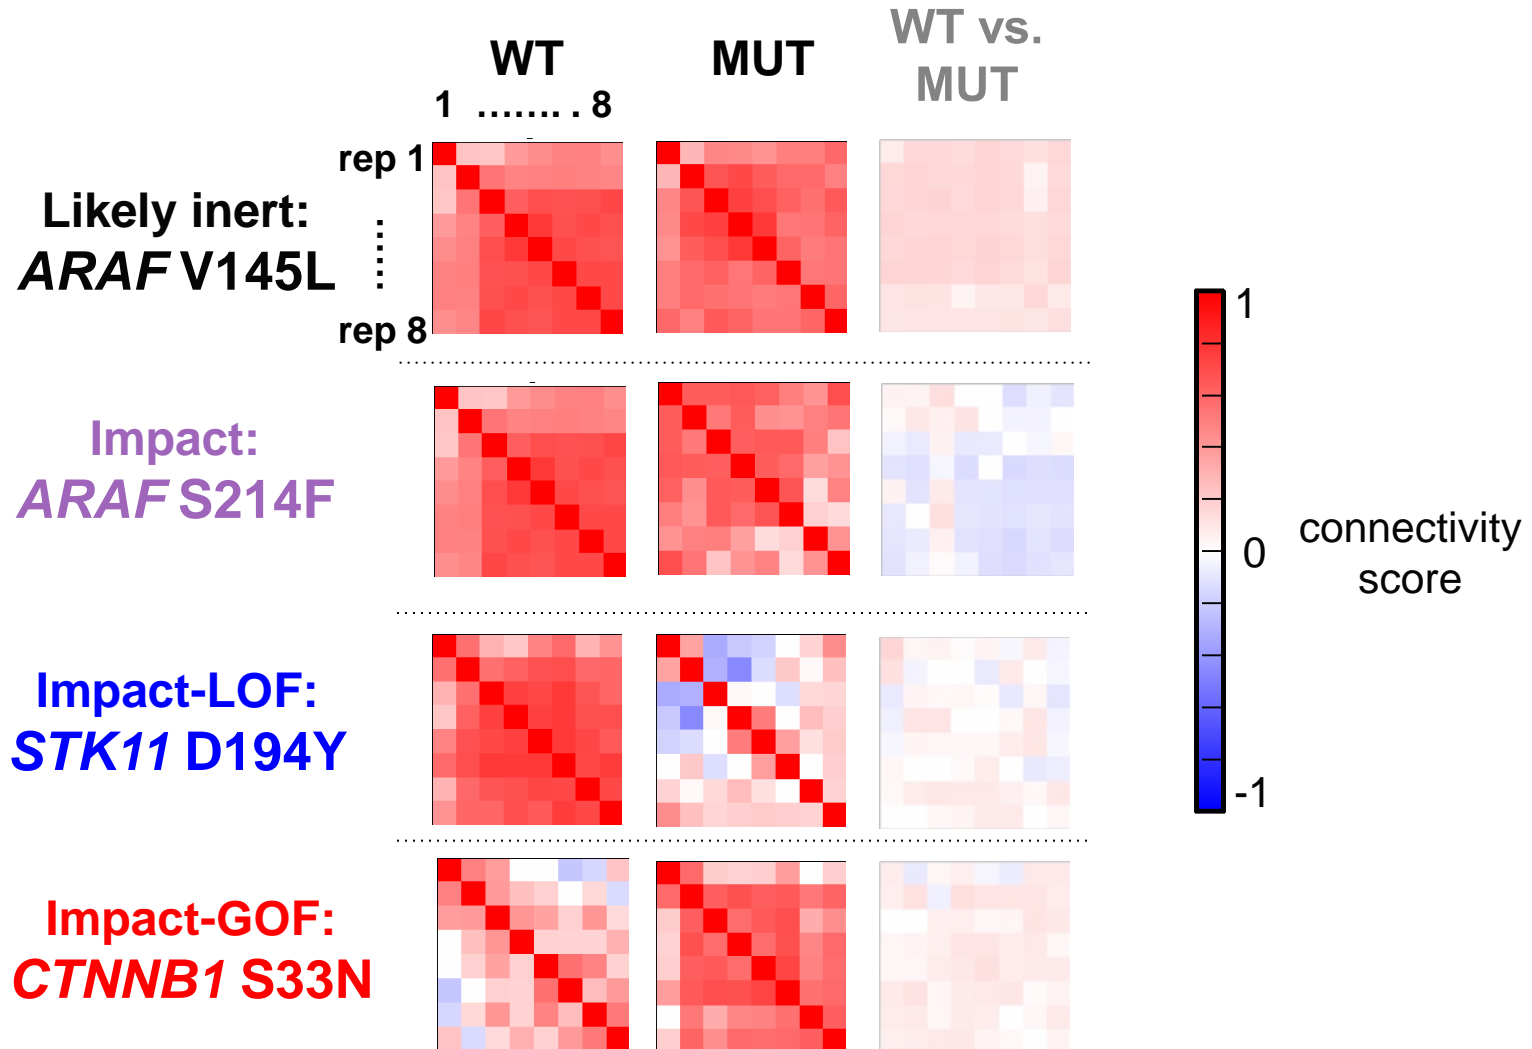

Functional  
impact:  
*ARAF* S214F

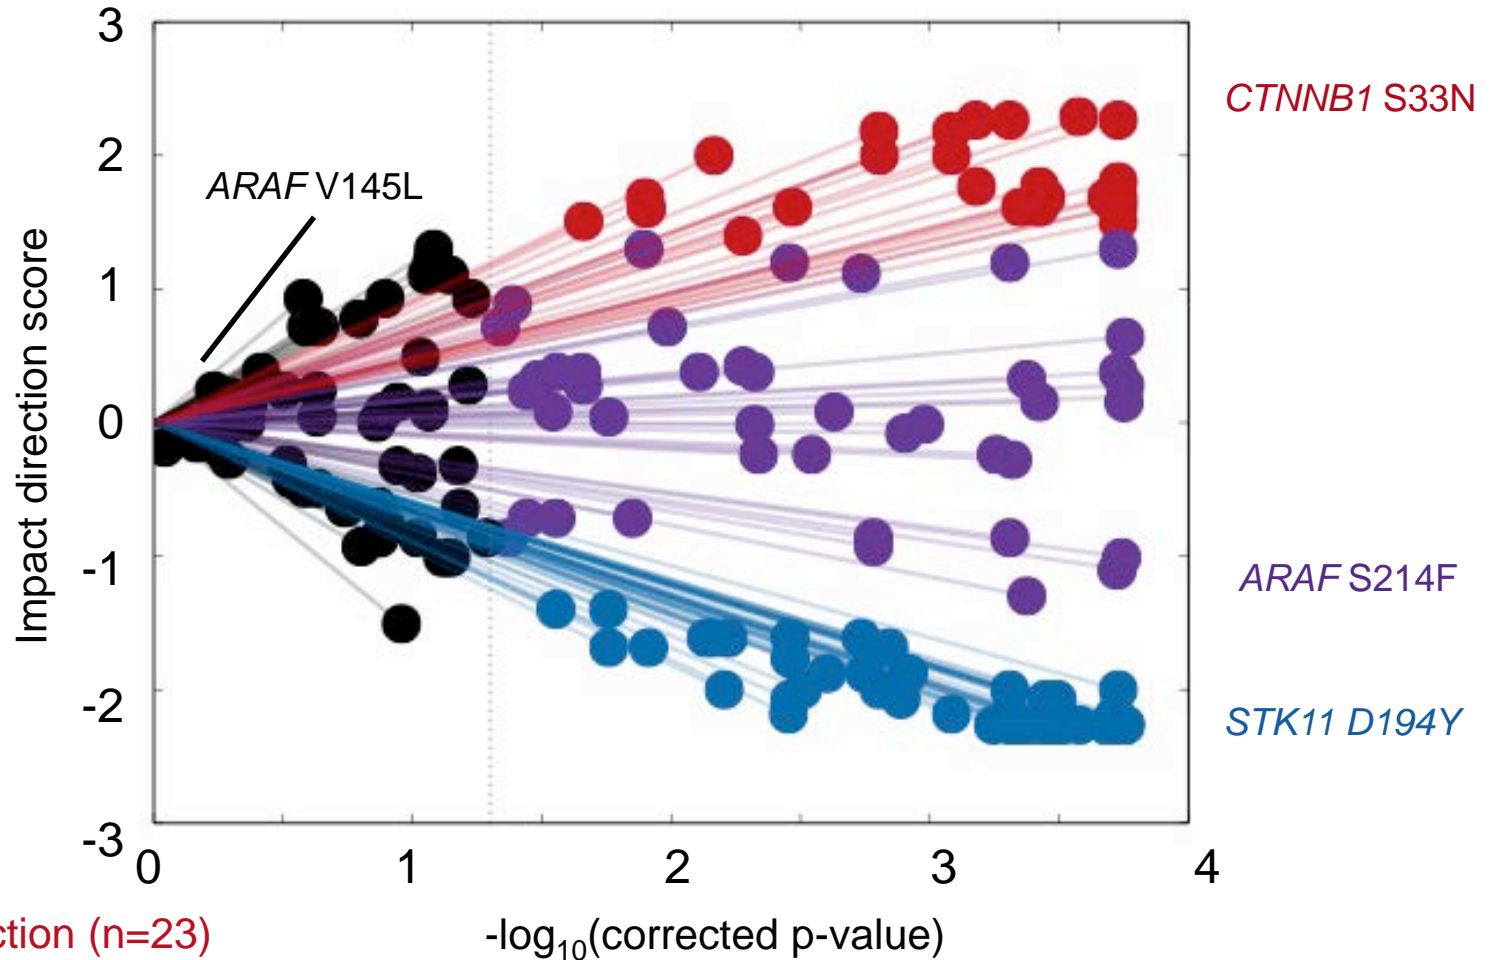

# Variant impact prediction is determined by a Kruskal-Wallis test (FDR 5%)

# Impact direction score can predict loss-of-function or gain-of-function change

# Sparkler plot of variant impact phenotyping for 151 lung cancer somatic mutations

- Gain-of-function (n=23)
- Loss-of-function (n=49)
- Impact (n=34)
- Likely inert (n=45)

# How do we know these predictions are correct?

- 1) Literature Benchmarks
  - 100% accuracy with 21 previously studied mutations
- 2) Subsampling from high replicate experiment to assess false positive rate
  - FDR 5% cutoff gives 4.84% false positive calls
- 3) Correspondence with genetic patterns (e.g. hotspot)

# Functional mutation in *FBXW7* is adjacent to a hotspot mutation

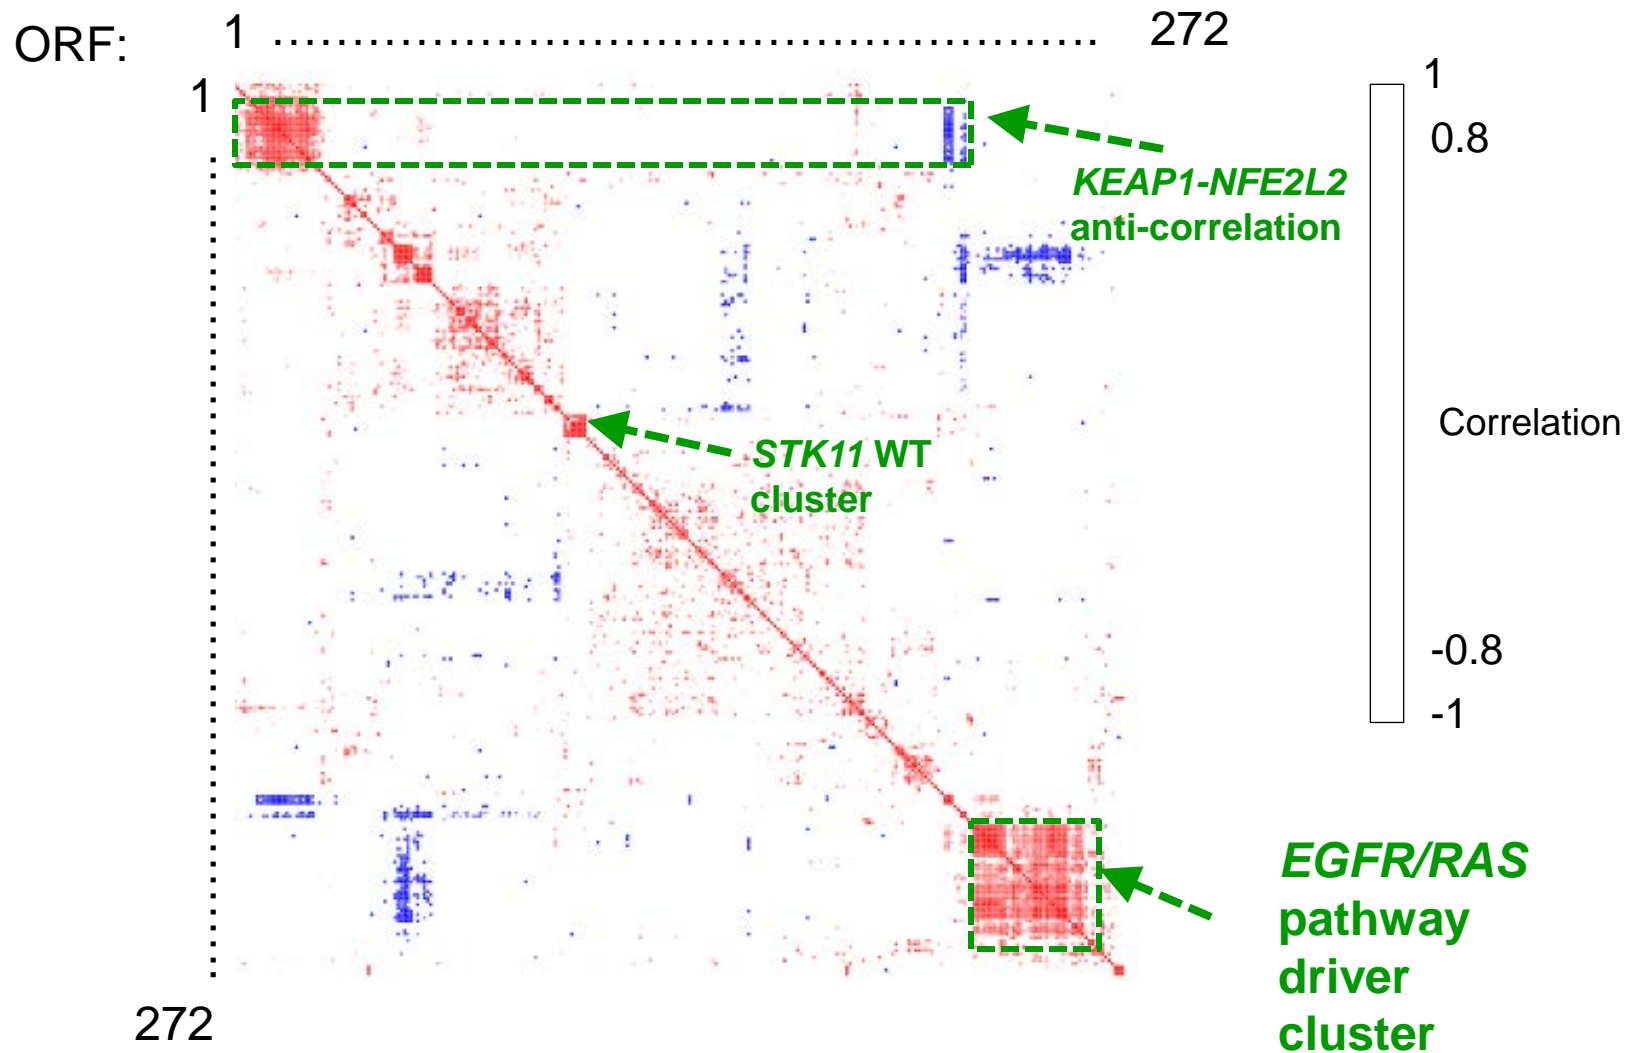

# How do we know these predictions are correct?

- 1) Literature Benchmarks
- 2) Simulation to assess false positive rate
- 3) Correspondence with genetic patterns (e.g. hotspot)
- 4) Signatures are similar to alleles of known gene function

# Identification of major transcriptional classes of lung adenocarcinoma genes

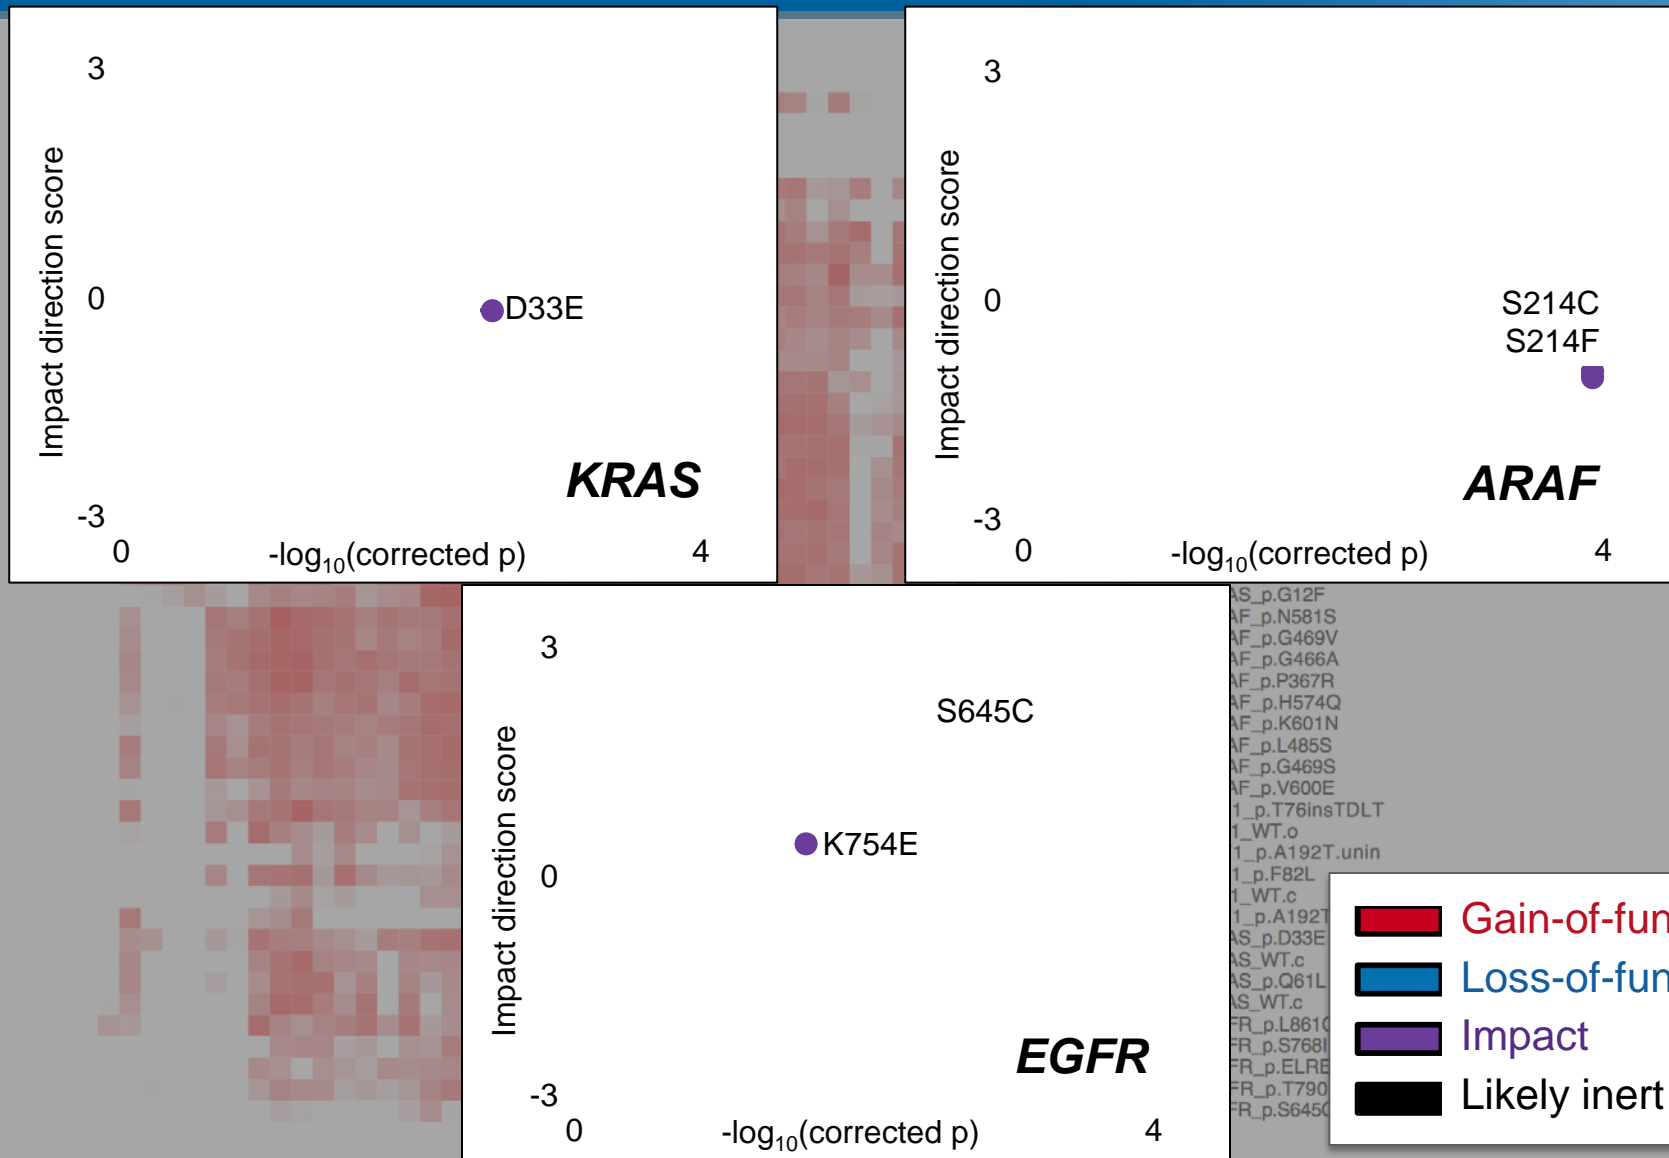

# Rare variants cluster with known EGFR/RAS pathway drivers

BRAF\_p.G466E  
BRAF\_p.A762E

# Rare variants cluster with known EGFR/RAS pathway drivers

# Unique signature of a rare non-canonical *EGFR* mutation is currently being investigated

## *EGFR* variants

H1129Y

*EGFR*

Non-canonical signature

*EGFR/RAS* cluster

# How do we know these predictions are correct?

- 1) Literature Benchmarks
- 2) Simulation to assess false positive rate
- 3) Correspondence with genetic patterns (e.g. hotspot)
- 4) Signatures are similar to alleles of known gene function
- 5) Orthogonal assays
  - Genetic rescue screens, multiplex tumor xenografts, cell morphologic profiling

# Variant impact phenotyping using a gene-agnostic assay

- Variant impact phenotyping is critical for understanding and treating cancer and other diseases.
- Gene-agnostic bioassays can more rapidly characterize variant impact
- This approach can be used for any gene, regardless of disease type and regardless of knowledge of gene function.
